- Introduction
- What you know
- What you have
- What you are
- Where you are
- Multi Factor Authentication

- **Definition:** Authentication is the binding of an identifier to a subject.
- The subject must provide information to enable the system to confirm the relation between subject and identifier.
- The goal of an authentication system is to ensure a correct identification of entities.

[Bi05, modified]

- The information comes from one (or more) of the following:
 - What the subject knows
 - PIN, passwords, pass-phrases, secret information
 - What the subject has
 - Keys, tokens, smart cards
 - What the subject is
 - Fingerprints, iris, retinal characteristics
 - Where the subject is
 - In front of a particular terminal, located by a particular radio receiver

[Bi05]

Authentication Process

- The authentication process consists of:
 - Obtaining authentication information from the subject
 - Analyzing the data
 - Determining if data is associated with that subject
- The computer must store some information about the subject.
- A mechanism for data management is required.

- Introduction
- What you know
- What you have
- What you are
- Where you are
- Multi Factor Authentication

- Passwords are the typical example of an authentication mechanism based on **what you know**.
- A password is information associated with an entity that confirms the entity's identity.
- **Example:** each user chooses a sequence of 8 digits as a password. Then A (the set of possible passwords) has 10^8 elements (from "00000000" to "99999999").

Attacking a Password System

- Threatening the subject
- Password guessing
- Password spoofing
- Social engineering

Threatening the Subject

- **Exhaustive search (a.k.a. brute force):** try all possible combinations of valid symbols, up to a certain length.
- **Intelligent search:** search through a restricted name space, e.g. try passwords that are somehow related with a user or generally popular.
 - Example: Dictionary attack

- Set a password:
 - If no password is set, the attacker is even spared the trouble of guessing one.
- Change default passwords
- Password length
 - To thwart exhaustive search, a minimal password length should be prescribed.
- Password complexity
 - Mix upper and lower case symbols and include numerical and non alphabetical symbols.
- Avoid obvious passwords
- Do not re-use passwords on different systems

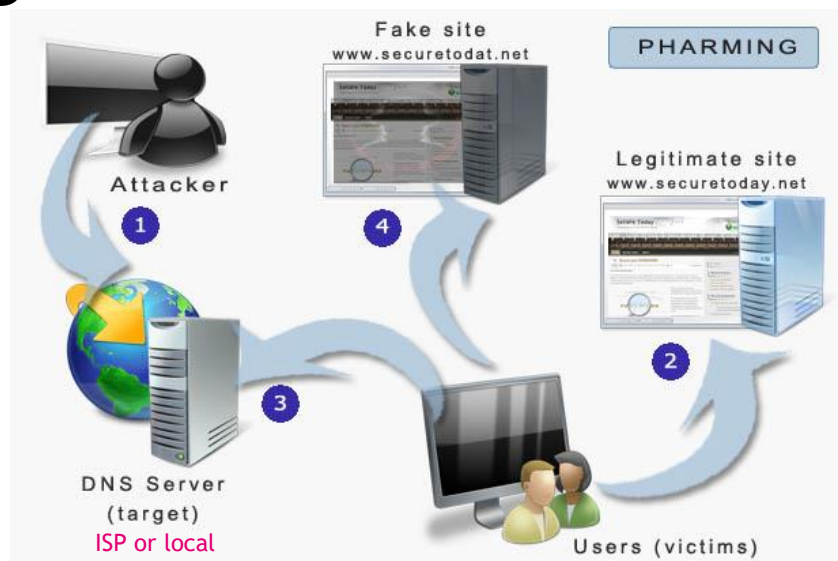

- Proactive password checkers
 - Search for weak passwords by administrator
- Password generation
 - Computer produces random passwords
- Password ageing
 - Set expiry date for passwords
- Limit login attempts
 - Lock account after multiple unsuccessful login events
- Inform user
 - Show time of last login, after a successful login.

- Identification and authentication through username and password only provide *unilateral authentication*.
- Does the user know who has received the password? -> **No**
- The user has no guarantees about the identity of the party at the other end of the line.

Password Spoofing

- The attacker runs a program that presents a fake login screen.
- An unsuspecting user tries to login at that terminal.
- The victim is asked for username and password.
- These are then stored by the attacker.
- Login is aborted with a (fake) error message and the spoofing program terminates.
- Often, the user is then redirected to the real login screen.

- When users ask for an IP address to match a URL, a wrong one is provided.
- Attack against **DNS server or user's PC.**

Source: <http://www.securetoday.net/>

- When users try to access the attacked website they are redirected to the fake site

- Displaying the number of failed logins:
 - If your 1st login fails but you are told at the 2nd attempt that there has been no unsuccessful login attempt, you should become suspicious.
- Trusted path:
 - Example: CTRL+ALT+DEL in Windows XP
Guarantee that the user is communicating with the operating system and not with a spoofing program.
- Mutual authentication:
 - The system could be required to authenticate itself to the user.

social engineering: n.

Term used among crackers (...) for cracking techniques that rely on weaknesses in wetware rather than software; the aim is to trick people into revealing passwords or other information that compromises a target system's security. Classic scams include phoning up a mark who has the required information and posing as a field service tech or a fellow employee with an urgent access problem. (...)

The Jargon File,

Staff give up passwords for chocolate bar

A new survey has discovered just how unconcerned employees are about IT security, with more than 71% of those questioned willing to divulge their computer password for nothing more than a chocolate bar.

The survey asked workers a series of questions including "what is your password?" at which 37% immediately gave it up. A further 34% revealed their password after some minor additional interrogation. Of the 172 office workers surveyed, the vast majority had passwords based on some easily uncovered aspect of their lives, such as family name or favourite football team, but the most common password was found to be 'admin.'

Hot on the heels of these revelations came a DTI survey, which revealed security breaches are, unsurprisingly, on the increase. One third of all UK businesses and two-thirds of large businesses had a security incident that

involved loss of data (excluding viruses), with the average cost to a business of a serious security incident set at £7,000 to 14,000 and a loss of four days of productivity.

Another serious concern was the discovery businesses were spending less than 3% of their IT spend on security and, though the majority of businesses understand the need for anti-virus software, most of them did not update the software often enough.

Stephen Timms, government minister for e-commerce, announced the results with the caveat that the context of the survey had changed. "UK companies are now using the internet as a routine part of business, but with the rapid adoption of e-business comes huge risks, and those risks are not being managed."

A full copy of the findings – and we urge you to read them – can be found at www.security-survey.gov.uk

- Introduction
- What you know
- What you have
- What you are
- Where you are
- Multi Factor Authentication

- The user has to present a physical object to be authenticated.
- Classic example: a key

- A card or identity token used to control access are examples of such a key.

What You Have (II)

Hardware Token

- Known also as Security Token, Authentication Token.
- Widely used as *unconnected* tokens

Smart Card

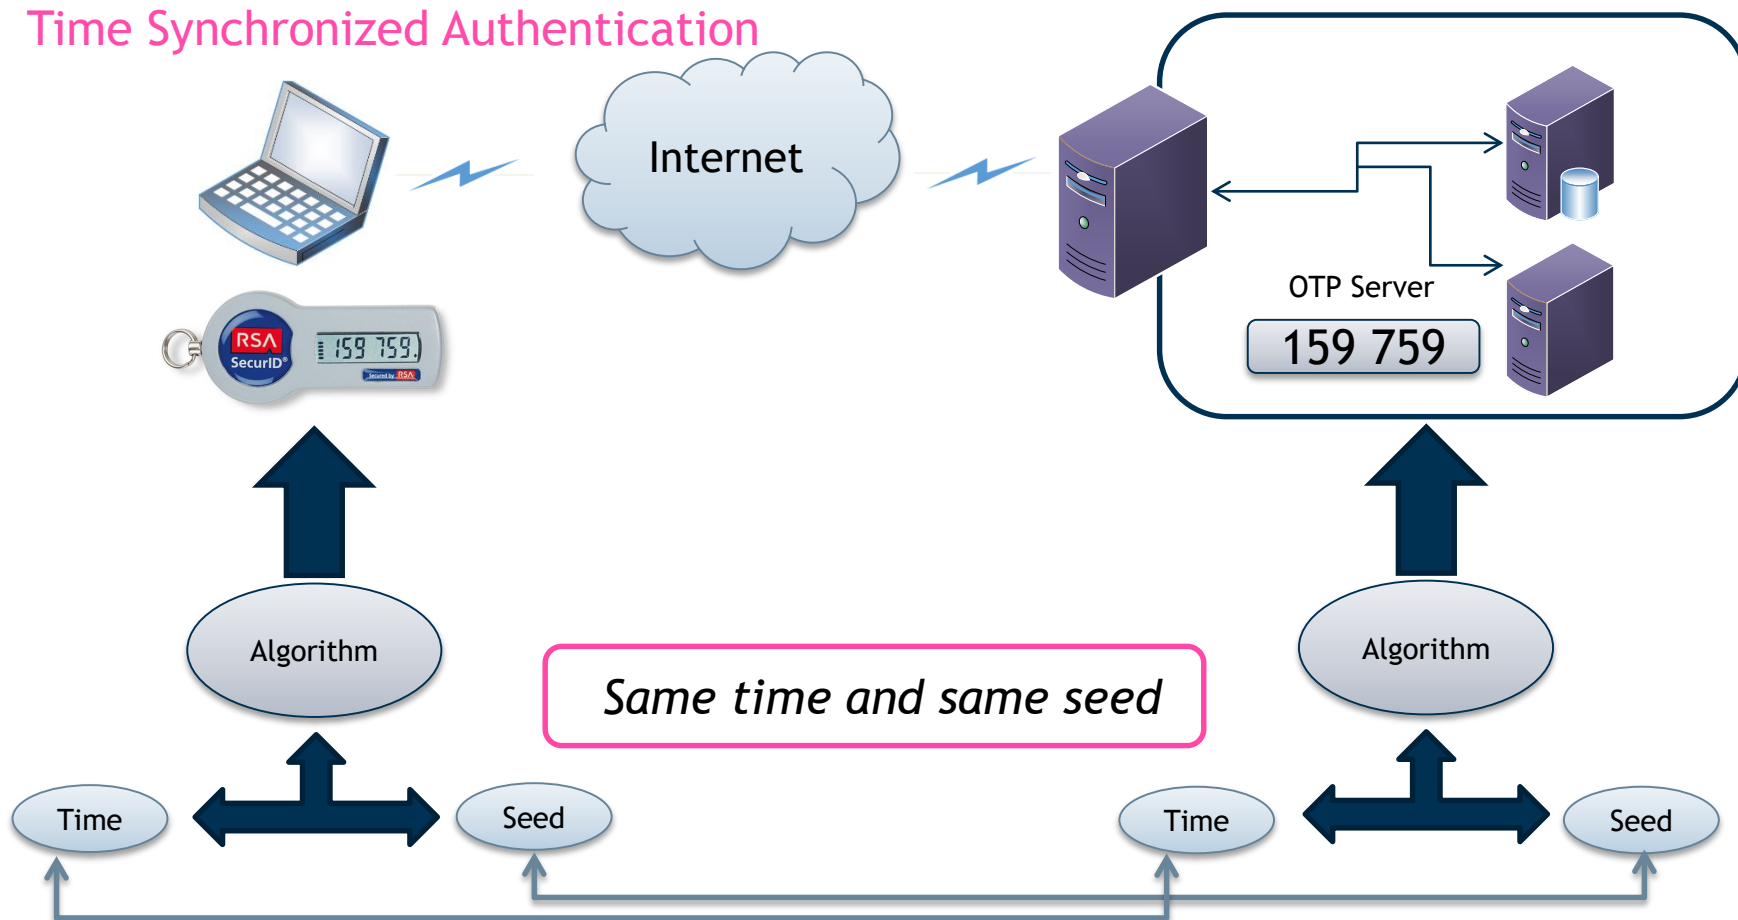

- Smart cards are an example of *connected* tokens.
- Low cost, strong security mechanisms

Security Tokens

One-time Passwords (OTP)

Time Synchronized Authentication

- A physical token can be lost or stolen.
- Anybody who is in possession of the token has the same rights as the legitimate owner.
- Combinations with PIN or other information about the legitimate owner are used.
- However, this does not eliminate the risk.

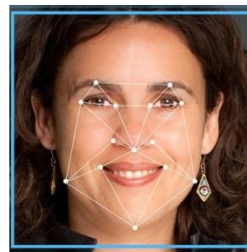

- Introduction
- What you know
- What you have
- What you are
- Where you are
- Multi Factor Authentication

- Identification by physical attributes is as old as humanity.
- Biometrics is the automated measurement of **biological** or **behavioural** features.
- Biometric systems **provide a percentage of similarity between samples**, i.e., an individual's identity is confirmed only if the resulting percentage is above a **predefined threshold**.

Physiological Biometrics

Fingerprint

Facial

DNA

Hand

Lip print

Iris &
Retina

- It distinguishes the unique impressions of **ridges and valleys** made by an individual's finger.
- The uniqueness can be determined by the pattern of ridges and valleys, as well as minutiae points.
- **High accuracy:** although spoiled readings occur from time to time.
- Fingerprint features can be obtained with a fingerprint sensor.

- It identifies the location, shape and size of random patterns in the external iris of the eye; it transforms the iris rim into a rectangular shape texture
- **High accuracy:** The probability of two irises producing the same code is nearly impossible.
- Iris patterns are obtained through a video-based image acquisition system.

- It captures a sequence of images, and extracts distinct individual features such as **eye socket position** (upper outlines), **space between cheek bones**, etc.
- **Medium accuracy:** other features such as hair and glasses and non-controlled scenarios (e.g., low light) make the recognition harder.
- Facial features can be obtained through simple store-bought camera.

Behavioral Biometrics

Voice

Keystroke Dynamics

Signature

Gait

- Authentication by voice, also called *speaker verification* or *speaker recognition* involves recognition of a speaker's voice characteristics.
- It analyses **power and spectral samples** of the speech, building a statistical pattern from them.
- **Low to medium accuracy:** the system needs to be trained first, it is susceptible to noise and changes in the voice.
- Voice features can be obtained with a microphone.

- It identifies user's typing pattern. It measures and compares the series of user specific timing events also known as “typing *signature*” based on
 - Keystroke intervals
 - Keystroke pressure
 - Where the key is stuck (on the edge or in the middle)
- Two different approaches
 - *Static* - happens once in the beginning of authentication
 - *Dynamic* - happens continuously (more secure)
- Samples could be taken either from conventional keyboards or from touch screens (key tap dynamics).
- **Low to medium accuracy:** FRR/FAR can be adjusted by changing the acceptance threshold **at the individual level**

[Bi05]

- Patterns will hardly ever match precisely.

false positives and false negatives

- If data can be copied by a potential attacker, identity fraud can occur.
- Replay attacks are possible.
- Biometric attribute can not be **revoked** easily.

- Introduction
- What you know
- What you have
- What you are
- Where you are
- Multi Factor Authentication

Location Based Authentication

- Geodetic location, as calculated from a location signature, adds a fourth and new dimension to user authentication and access control.
- The physical location of a particular user or network node at any instant in time is uniquely characterized by a location signature.
- This signature is created by a location signature sensor (LSS) from the microwave signals transmitted by the twenty-four satellite constellation of the Global Positioning System (GPS).
- An entity in cyberspace will be unable to pretend to be anywhere other than where its LSS is actually situated.

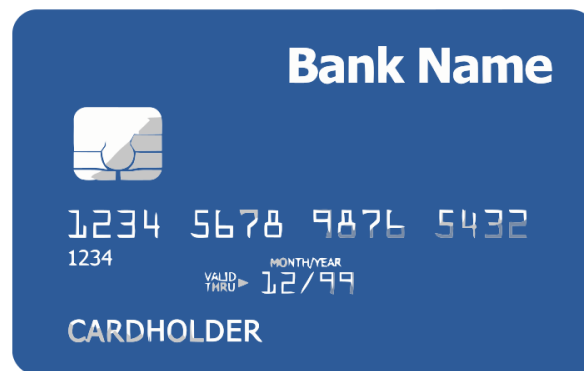

[DeMa96]

- Introduction
- What you know
- What you have
- What you are
- Where you are
- Multi Factor Authentication

Multi Factor Authentication

- Authentication mechanisms can be combined, or multiple methods can be used (Multi Factor Authentication).
- The multiple layers of authentication require an attacker to know more, or possess more, than is required to spoof a single layer.

- Automatic Teller Machines (ATM)
- Combination of security token (EC- card) and password (PIN)
